What makes region attractive for worker?

Yuga Hikida

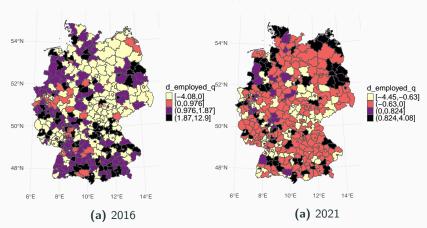

TU Dortmund University

Background

- Determinant of migration of worker (Moretti 2011)
 - Labour market condition
 - net wage, unemployment rate...
 - Amenities
 - public goods, facilities...
- Empirically analyse what makes region attractive for worker.
- Previous studies: migration decision from various factors from both of the channels (Buch et al. 2014; Hakim et al. 2022).
 - No single strong determinants of migration.

Data

- Focus on changes in employees in each region over time.
- $\quad \quad \mathbf{y}_t := 100 \times \{\log(\mathsf{employed}_t) \log(\mathsf{employed}_{t-1})\}$
- Period: 2016 2021
- All data is obtained from https://www.inkar.de/

3

Modalities

- splm package (Millo and Piras 2009) is used for all the estimation.
- Maximum likelihood method is used.
- Statistical testing: 5% significance level.

Explanatory variables

Variable name	description
GDP per employed	GDP in €1,000 per employed person
Unemployement rate	Share of unemployed people in %
Land price	Average purchase values for building land in € per m2
Proportion of foreigners	Proportion of foreigners to residents in %
Amount of waste	Amount of waste disposed of or treated per inhabitant in kg
Hospital beds	Hospital beds per 1,000 inhabitants

- Some variables are transformed such that scale of all the variables are roughly same.
- ullet Denoted as X in the following slides.

Basic panel data model

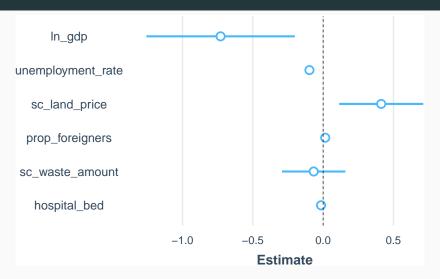

For region i = 1, ..., N, time t = 1, ..., T:

$$\begin{split} y_{it} &= \alpha + \beta^T X_{it} + u_{it} \\ u_{it} &= \mu_i + \nu_{it} \\ \mu_i &\stackrel{\text{iid}}{\sim} (0, \sigma_\mu) \\ \nu_{it} &\stackrel{\text{iid}}{\sim} (0, \sigma_\nu) \end{split}$$

where
$$X_{it} = [x_{it1},...,x_{itK}]^T$$
 and $\beta = [\beta_1,...,\beta_K]^T.$

 μ_i is a group specific effect ("random effect") differs across region which is modelled independently constant over time.

Result

- Counter-intuitive result from economic theory
- Potential model misspecification?

Adding autoregressive error term

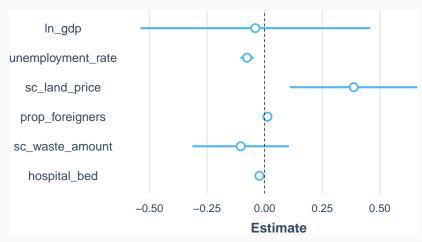

$$\begin{split} y_{it} &= \alpha + \beta^T X_{it} + u_{it} \\ u_{it} &= \mu_i + \lambda \sum_{j=1, j \neq i}^N w_{ij} u_{jt} + \nu_{it} \\ \mu_i &\stackrel{\text{iid}}{\sim} (0, \sigma_\mu) \\ \nu_{it} &\stackrel{\text{iid}}{\sim} (0, \sigma_\nu) \end{split}$$

where $|\lambda|<1$ is spatial autoregressive parameters and w_{ij} is the i,j element of $N\times N$ spatial weight matrix.

Now error term is decomposed into three parts: group specific part, autoregressive part and idiosyncratic part.

Result: Autoregressive error model

■ LM test under the null hypothesis $\lambda=0$ suggests existence of spatial autocorrelation \to estimate model with autoregressive error.

Spatial lag of the dependent variable

$$\begin{aligned} y_{it} &= \alpha + \rho \sum_{j=1, j \neq i}^{N} w_{ij} y_{jt} + \beta^T X_{it} + u_{it} \\ u_{it} &= \mu_i + \lambda \sum_{j=1, j \neq i}^{N} w_{ij} u_{jt} + \nu_{it} \\ \mu_i &\stackrel{\text{iid}}{\sim} (0, \sigma_{\mu}) \\ \nu_{it} &\stackrel{\text{iid}}{\sim} (0, \sigma_{\nu}) \end{aligned}$$

- $|\rho| < 1$ is the effect of spatially lagged dependent variable.
- Consider so called direct impact and indirect effect (explained later).

Result: Spatial lag model + spatially correlated error

- Difficult to interpret directly (next slide)
- Statistical significance of lagged term implies potential model misspecification of other two models.

Direct and indirect effect

Focus on single time. Matrix form of the model is given by

$$\begin{split} y &= \alpha + \rho W y + X \beta + u \\ y &= (I - \rho W)^{-1} X \beta + (I - \rho W)^{-1} (\alpha + u) \\ \tilde{y} &:= (I - \rho W)^{-1} X \beta \\ &= \sum_{k=1}^K (I - \rho W)^{-1} I \beta_k X_k := \sum_{k=1}^K S_k(W) X_k \end{split}$$

where $X_k = [x_1, ..., x_{Nk}]^T$.

- $\bullet \ \, {\rm Direct\ effect} = {\rm impact\ of}\ x_{ki}\ {\rm on}\ y_i$
 - Diagonal element of $S_k(W)$.
- $\quad \textbf{Indirect effect} = \textbf{impact of } x_{kj}, j \neq i \textbf{ on } y_i$
 - Off-diagonal element of $S_k(W)$. "Spatial spillover".
- Average over region / time to obtain summary measures (Rüttenauer 2024).

Result: Direct and indirect effect

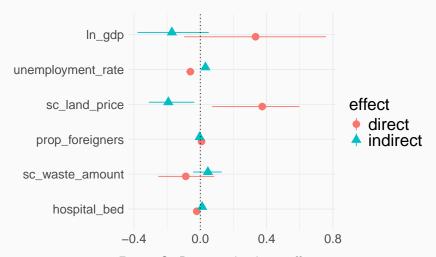

Figure 3: Direct and indirect effect

Economic interpretation

- Positive direct effect / negative spillover in GDP per capita.
 - Worker move to region with high GDP.
- Negative direct effect / positive spillover in unemployment rate.
 - Worker move out of region with high employment rate.
- Positive direct effect / negative spillover in land price.
 - People move to region with high rent?
 - Could be due to amenities associated with high rent.
 - Urban area, more amusement facilities etc.
